Tip

Learning Outcomes

At the end of this computer practical, students should be able to:

- Calculate Binomial probabilities
 - Using your calculator;
 - R commands;
 - R simulations.
- Calculate Poisson probabilities
 - Using your calculator;
 - R commands;
 - R simulations.

Computer lab

The first part of this prac involves walking through some exercises with your demonstrator. These may involve some hand calculations, which you can do using R, your calculator, or in your head.

The Binomial Distribution

Notation

Factorials: $n! = n(n-1)(n-2)\dots(3)(2)(1)$ for $n \geq 1$ and $0! = 1$.

Binomial coefficients: $\binom{n}{x} = \frac{n!}{x!(n-x)!}$ for $x = 1, 2, 3, \dots, n$

The **Binomial distribution** models a context in which we have a fixed number n of independent Binary trials and a fixed likelihood of a success at each trial $p = P(\text{success})$.

X = the number of successes in n trials $\sim \text{Bin}(n, p)$

Probability distribution function: $P(X = x) = \binom{n}{x} p^x (1-p)^{n-x}$ for $x = 1, 2, 3, \dots, n$

Cumulative distribution function (CDF): $F(x) = P(X \leq x)$.

Exercise 1 - Walk through

With your neighbour, discuss how coin tossing is related to the Binomial distribution?

Exercise 2 - Walk through

Practicing using the Binomial distribution formula

- Calculate $4!$, $3!$, $2!$ and $1!$.

$$4! = 4 \times 3 \times 2 \times 1$$

Now you calculate the rest

- Show that

$$\binom{4}{0} = 1, \binom{4}{1} = 4, \binom{4}{2} = 6, \binom{4}{3} = 4, \binom{4}{4} = 1$$

$$\binom{4}{0} = \frac{4!}{0!(4-0)!} = \frac{4!}{4!} = 1$$

$$\binom{4}{1} = \frac{4!}{1!(4-1)!} = \frac{4!}{1! \times 3!} = \frac{4 \times 3 \times 2 \times 1}{1 \times 3 \times 2 \times 1} = \frac{4}{1} = 4$$

Now you calculate the rest!

Note you can also calculate this using the nCr option on your calculator - watch this [YouTube video](#) which gives a nice demonstration with some elevator music in the background to relax you.

Exercise 3 - Walk through

Collaboration - Simulate the Binomial Distribution by Coin Tossing

- Choose a partner and together toss a coin 4 times counting the number of heads (use [Flip a coin](#) if you don't have a coin). Record the number of heads in an excel spreadsheet called (Simulation 1) and set out a table in excel similar to below. Now repeat this process 19 more times.

Simulation	Toss 1	Toss 2	Toss 3	Toss 4
1				
2				
3				
...				
...				
20				

- Tally up the frequency of each number of heads and fill in a table similar to the following in excel.

Number heads x	0	1	2	3	4	Total
Frequency						20

- Now fill in the probability distribution in excel = the proportion of number of heads in all simulations i.e. number of simulations with 0 heads/20, number of simulations with 1 head/20, number of simulations with 2 heads/20,....

Number heads x	0	1	2	3	4	Total
Probability $P(X = x)$						1

- now see if you can make a barplot in Excel of the above table [Excel instructinos](#)

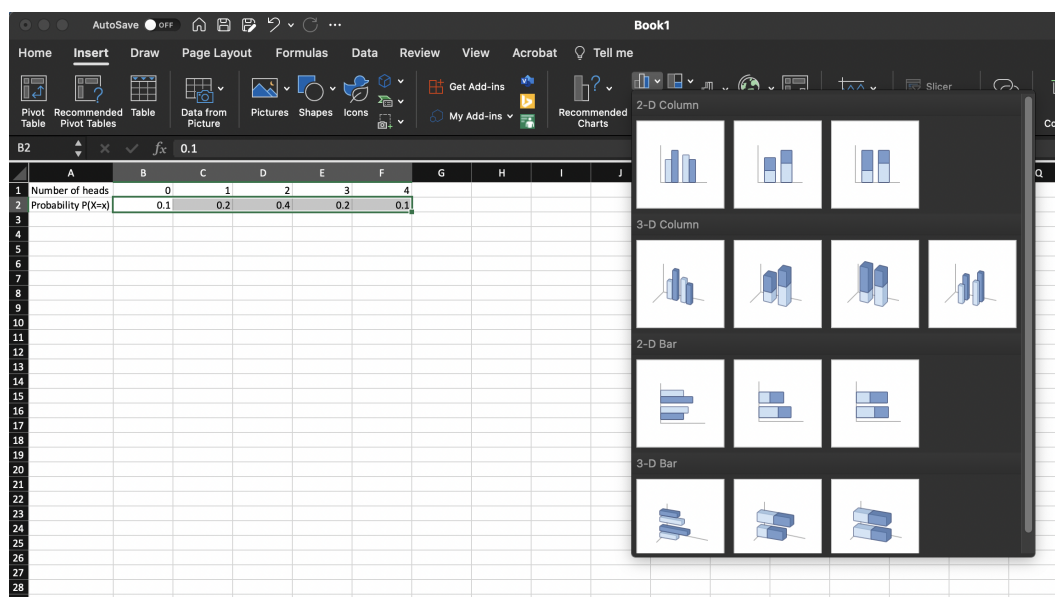

Figure 1: Barchart 1

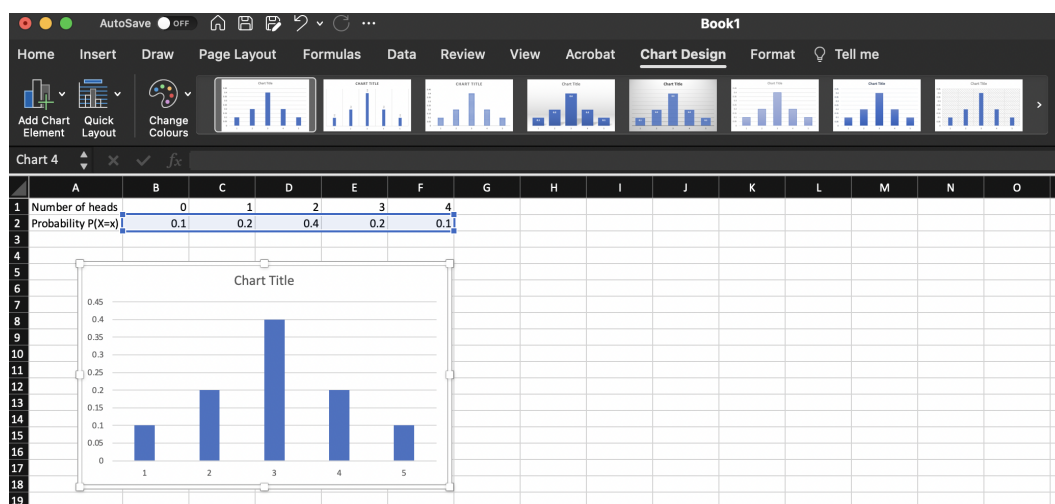

Figure 2: Barchart 2

Question: With your **stats** partner, discuss the shape of the distribution, is it what you would expect to see and compare this to what the barplot you made in excel, are they similar?

Exercise 4 - Walk through

Now we will use R to simulate 4 coin tosses representing 1 as heads and 0 as tails. Note that I have withheld the output to avoid “spoiling” the surprise.

```
coin <- c(0,1) # vector representing coin tosses c(tails, heads)
set.seed(1) # makes sure we all get the same answer i.e. we use the same randomly generated numbers
tosses <- sample(coin, size = 4*20, replace = T, prob = c(0.5, 0.5)) # this randomly picks a 0 or 1 from coin and the
dim(tosses) <- c(20,4) # This creates a data frame with 4 columns and 20 rows that represents the 20 trials of 4 coin
tosses ## this prints the result
NumHeads <- rowSums(tosses) ## this sums the number of heads in each trial
NumHeads # this prints the results
```

- The table function tallies each of the numbers of heads for each simulation. In each trial (4 tosses) How many times did you toss no heads, how many times did you toss 1 head, how many times did you toss 2 heads, how many times did you toss 3 heads and how many times did you toss 4 heads?

```
Freq_table <- table(NumHeads)
Freq_table
```

The prob.table function divides each frequency by 20 i.e. $P(X = 0) = 2/20$

```
prop.table(Freq_table)
```

- Now we can plot this. Notice how we customise the x-axis to ensure that 0 is displayed as even though there may be no instances where we got zero heads, it is still a possibility even if the probability is low. for this we use the argument , xaxt = “n” and then draw customised axis labels using the axis function.

```
plot(prop.table(Freq_table), ylab="P(X=X)", xlab = "x", xlim = c(0,4), xaxt = "n")
axis(1, at = 0:4)
```

Exercise 5

Repeat exercise 4, but this time change the 'prob = c(0.5, 0.5)' to 'prob = c(0.3, 0.7)'.

Question: What happens to the shape of the distribution? What type of coin does this change in probability represent?

Exercise 6

Repeat exercise 4, but this time change the `set.seed(1)` to `set.seed(123)`.

Question: What happens to the frequency table 'Freq_table' why do you think it might change?

Exercise 7

Six calves were born after artificial insemination (AI) with regular semen. Assuming that the probability for either being male or female is 0.5,

Question: What is the probability that all 6 are male?

$X = \text{number of male calves} \sim \text{Bin}(n = 6, p = 0.5)$ $P(X = 6) = \binom{6}{6} 0.5^6 (1 - 0.5)^{6-6} = 0.015625$

or in R we can calculate using the `dbinom` function which calculates the exact probability of having 6 male calfs born

```
dbinom(6,6,0.5)
```

Question: What is the probability that more than 4 calves are female?

NOTE $P(\text{more than 4 calves are female}) = P(\text{less than 2 calves are male}) = P(X=0) + P(X=1)$

$= \binom{6}{0} 0.5^0 (1 - 0.5)^{6-0} + \binom{6}{1} 0.5^1 (1 - 0.5)^{6-1} = 0.109375$

or in R

```
1-pbinom(4,6,0.5)
```

Question: What are your assumptions? What is a more accurate estimate of the $P(\text{male calf})$?

[Beef Article](#)

Assumptions: Each of the births is independent and $P(\text{male calf} = 0.5)$. (In reality, it is 1.06 males per every female born in large populations of cattle, which gives $p = 0.5145631$. See article link.)

Using the updated probability $p = 0.5145631$ and using R recalculate

Question: What is the probability that all 6 are male?

Question: What is the probability that more than 4 calves are female?

Question: Finally, calculate what is the probability that exactly 4 females are born?

The Poisson Distribution

The Poisson distribution is often used to model the number of expected events that occur during a given unit of time.

Remember if $X \sim Po(\lambda)$ then

$$P(X = x) = \frac{\lambda^x e^{-\lambda}}{x!} \text{ for } x = 0, 1, 2, \dots \text{ and } \lambda > 0$$

Exercise 1 - Walk through

Lets take a look at an example. Let us assume that **on average** 5 shoppers enter a store each hour. Say the shop is open for 10 hours per day, what would a typical day look like. Assuming that the number of visits follows a Poisson distribution i.e. If $X \sim Po(\lambda)$, and because we know $\lambda = 5$ and $n = 10$, we can simulate this in R using the following:

```
shoppers <- rpois(10, 5)
shoppers
```

Question: Take a look at the minimum and maximum number of shoppers generated by the model and discuss with your neighbour how you, as a shop owner, might use this information?

Question: Now run the simulation for a full 5 day week, is there any change?

Question: Now suppose as a shop owner you are concerned that your shop assistant might get overwhelmed if more than 10 shoppers come in, in any one hour period, what is the probability of this?

Exercise 2

We also often say that the Poisson Distribution is good for modeling rare events. For example, recent work in *Drosophila* suggests the spontaneous rate of deleterious mutations is 1.2 per diploid genome.

Open the following article and read the abstract and then search the word poisson and read the final two sentences of this paragraph.

[Nature article](#)

Assume that X = the number of deleterious mutations $X \sim Po(1.2)$.

Question: What is the probability that an individual has 0 mutations?

$$P(X = 0) = \frac{1.2^0 e^{-1.2}}{0!} = 0.3011942$$

Or in R

```
dpois(0,1.2)
```

Question: What is the probability that an individual has less than or equal to 2 mutations?

$$P(X \leq 2) = P(X = 0) + P(X = 1) + P(X = 2) = \frac{1.2^0 e^{-1.2}}{0!} + \frac{1.2^1 e^{-1.2}}{1!} + \frac{1.2^2 e^{-1.2}}{2!} = 0.8794871$$

Or in R

```
ppois(2,1.2)
```

More recent research found that the average spontaneous rate of deleterious mutations was actually 1.4 per diploid genome. Using R recalculate the following.

Question: What is the new probability that an individual has 0 mutations. How does this compare to the former probability, what does this suggest?

Question: What is the new probability that an individual has less than or equal to 2 mutations. How does this compare to the former probability, what does this suggest?

Advanced exercise

From the tutorial we looked at Tomato germination. Use simulations to find approximate Binomial probabilities obtain an estimate of the probability of getting 7 or more germinating seeds, by doing simulations from a $Bin(8, 0.7)$ in R.

Remember that the exact probability is

```
1-pbinom(6,8,0.7)
```

```
[1] 0.2552983
```

- First try 10 simulations and fill out a similar table to below in excel. What is your estimate of the probability of 7 germinating seeds?

```
set.seed(123)
seeds <- rbinom(n = 10, 8, 0.7) # randomly generates 10 values from Bin(8,0.7)
seeds ## prints seeds
table(seeds)/10 # turns counts into probabilities
barplot(table(seeds)/10, xlab="Number Germinated x", ylab="Probability", col="green")
```

- Next try 100 simulations.

```
set.seed(123)
seeds <- rbinom(n = 100, 8, 0.7) # randomly generates 100 values from Bin(8,0.7)
seeds ## prints seeds
table(seeds)/100 # turns counts into probabilities
barplot(table(seeds)/100, xlab="Number germinated (x)", ylab="Probability", col="green")
```

- Now we will try 10000 simulations. What do you notice about the histogram?

```
set.seed(123)
seeds <- rbinom(n = 10000, 8, 0.7) # randomly generates 100 values from Bin(8,0.7)
table(seeds)/10000 # turns counts into probabilities
barplot(table(seeds)/10000, xlab="Number germinated (x)", ylab="Probability", col="green")
```

- Now we can compare the exact results and the simulated results by adding up the probabilities for 7 and 8 seeds germinating in each of the scenarios.

Note that the numbers will may differ slightly each time as they a randomly generated unless you set the same seed.

Number germinated	$P(X \geq 7)$
Exact method using R	
Simulation (n=10)	
Simulation (n=100)	
Simulation (n=10000)	

Question: Which of the simulations gives the closest result to the exact method, why do you think this is? - **try ask chatGPT** or use the **# q: What is ?** prompt if you have enabled copilot.
